

# Radius/Momentum Calculation for S444 Experiment

## February 2020 - Overview

Tobias Jenegger

## 0.1 The Setup

# 1 Geometry and relative position of the detectors in the beam direction

Here, the positions are given for the s444 and s467 experiments

z position of the MWPC0:  $z_{MW0} = -2520$  mm  
z position of the target:  $z_T = -684.5$  mm  
z position of the MWPC1 in front of the Twin-MUSIC:  $z_{M1} = 279$  mm  
z position of the middle of the Twin-MUSIC:  $z_{Twin} = 553$  mm  
z position of the MWPC2 after the Twin-MUSIC:  $z_{M2} = 854$  mm  
 $\alpha$  tilted angle of GLAD (14 degrees):  $= 0.244$  rad  
effective length of GLAD:  $L_{eff} = 2067$  mm  
z middle of GLAD  $z_{Gm} = 2577$  mm  
horizontal of the central path (18 degree)  $\theta_{out0} = \pi/10$  rad  
z position of the MWPC3 after GLAD  $z_{M3} = 5937$  mm  
z position of the ToFwall  $z_{ToFW} = 6660.2$  mm

Correspondence between the GLAD current and the magnetic field:  $I = 3584$  A,  $B = 2.2$  T

Positions of the TOFWPads:

1  $\Rightarrow$  Messel

27  $\Rightarrow$  Wixhausen

## 2 RUNS used for calibration = SWEEP RUNS without target

RUN	Beam ion	Beam Energy [AmeV]	GLAD current [A]	Comments
36	12C primary	400	1444	before broken motor, here we see that tof is about 5ns faster. So they probably changed the position of the TOFW afterwards
37	12C primary	400	1444	it has be seen that motor drive not working
38	12C primary	400	1444	tof is back with new gates *magnet sweep 1444A
39	12C primary	400	1498	
40	12C primary	400	1501	
41	12C primary	400	1501	stopped with 1558 A
42	12C primary	400	1558	
43	12C primary	400	1558	stopped with 1653 A
44	12C primary	400	1653

### 2.0.1 Other RUNS used for various checks:

RUN 70: 2 cm C target  
 RUN 80: 10.86 mm C target  
 RUN 81: 24.53 mm CH2 target  
 RUN 67: 24 mm CH2 target  
 RUN 68: 1 cm C target  
 RUN 79: 12.29 mm CH2 target  
 RUN 75: 21.98mm C target

### 3 Methods for flightpath reconstruction in the (x,z) plane

#### 3.1 The "Kickplane" method

3.1.1 From MW0 to the entrance of GLAD, the ion is following a straight line

The straight line trajectory from MW0 to entrance before glad is defined by:

⇒ one absolute value before GLAD

absolute = calibrated position in mm in the laboratory frame

To get the position, use the position given by one MWPCs (1 or 2)

⇒ the theta angle (theta\_in) before GLAD

Angle obtained from combining MWPC1 and MWPC2  
(to get higher precision the drift time in TWIM MUSIC could be used)

### 3.1.2 From entrance to the exit of GLAD, the effective trajectory is circular

The circular trajectory is defined by:

- ⇒ one absolute position before GLAD B and angle theta<sub>in</sub> (see: 3.1.1)
- ⇒ one absolute position at MWPC3

From this information the angle theta<sub>out</sub> is constructed in following steps:

1. Extend the line of flight of the ion before the GLAD.
2. The point of intersection with the "kickplane" (symmetry axis line of GLAD magnet) is the kickpoint C.
3. Draw a straight line between C and the absolute position at MWPC3 = M3.
4. theta<sub>out</sub> is the positive angle between the z-beam direction and the line between C and M3.

The curvature radius  $\rho$  is given by<sup>1</sup>:

$$\rho = \frac{L_{\text{eff}}}{2 \cdot \sin\left(\frac{\theta_{\text{in}}}{2} + \frac{\theta_{\text{out}}}{2}\right) \cdot \cos(\delta)}$$

With  $\delta$ :

$$\delta = \arctan\left(\left|\frac{\frac{\cos(\theta_{\text{out}}) - \cos(\theta_{\text{in}})}{\sin(\theta_{\text{out}}) + \sin(\theta_{\text{in}})} + \tan(\alpha)}{1 - \frac{\cos(\theta_{\text{out}}) - \cos(\theta_{\text{in}})}{\sin(\theta_{\text{out}}) + \sin(\theta_{\text{in}})} \cdot \tan(\alpha)}\right|\right)$$

The full derivation can be found in the appendix.

The circular trajectory is then given by:

$$\omega = 2 * \left| \arcsin\left[\frac{BD}{2 \cdot \rho}\right] \right|$$

with  $BD$  = length of the  $BD$  segment

### 3.1.3 After GLAD up to the TOFW, the trajectory is a straight line

The straight line trajectory from D to E is defined by:

<sup>1</sup>for consistency checks the  $\cos(\delta)$  term can be omitted, as it plays a minor role

- ⇒ the output angle from GLAD  $\theta_{out}$
- ⇒ one absolute position after GLAD in the laboratory frame M3

With this information the straight line trajectory length after GLAD can be measured. It starts at the exit point of GLAD D and follows the straight line (characterized by the angle  $\theta_{out}$  and the absolute position at MWPC3) until the intersection with the ToFW (middle position of the ToFWall  $z_{ToFW} = 6660.2mm$ , tilted angle =  $18^\circ$ ).

Finally the pathlength in the (x,z) plane from the target position to the ToFW is given by:

$$P = AB + \rho \cdot \omega + DE$$

where:

A = (x,z) position at the target point

B = (x,z) position at the GLAD entry point

D = (x,z) position at the GLAD exit point

E = (x,z) position where the constructed trajectory line hits the ToFW

The assumption for the "Kickplane" method is that the kickpoint for each event lies on the predefined Kickplane, the symmetry axis line of the GLAD magnet.

### 3.2 The "Fit-Track" method

For the "Fit-Track" method the assumption that the kickpoint C lies on the symmetry axis line of the GLAD magnet is rejected. Instead following algorithm is applied: <sup>2</sup>

1. Extend the line of flight of the ion before the GLAD.
2. Draw a line from the point MW3 to C (as constructed with the "Kickplane" method).
3. Now sweep the straight line after the kickpoint, leaving the position MW3 unchanged but sweeping the intersection point along the inline beam.
4. For each sweeping step plot  $\theta_{out}$  versus (d1-d2) where d1 is the distance between B and the point of intersection and d2 the distance between D and the intersection point accordingly.
5. 50 sweeping steps are performed.
6. Fit the final  $\theta_{out}$  versus (d1-d2) plot with linear least square fit.

---

<sup>2</sup>This algorithm is motivated from [https://www.blogs.uni-mainz.de/fb08-kernphysik/files/2018/09/PHDThesis\\_OlgaBertini.pdf](https://www.blogs.uni-mainz.de/fb08-kernphysik/files/2018/09/PHDThesis_OlgaBertini.pdf), section 3.4

7. Find the intersection of the abscissa. The corresponding  $\theta_{out}$  value is now the corrected one which should be used for the calculation of the radius.

### 3.3 The "Theta\_in correction" method

Here the "Kickplane" method is used and subsequently the  $\theta_{out}$  is corrected by  $\theta_{in}$ . That means:

$$\theta_{out\_corr} = \theta_{out} - \theta_{in}.$$

Consequently the  $\theta_{in}$  dependence of  $\rho$  vanishes (neglecting the  $\cos(\delta)$  term):

$$\rho = \frac{L_{eff}}{2 \cdot \sin\left(\frac{\theta_{in}}{2} + \frac{\theta_{out\_corr}}{2}\right)} = \frac{L_{eff}}{2 \cdot \sin\left(\frac{\theta_{out}}{2}\right)}$$

### 3.4 Final method: "Advanced Fit-Track" method

The same track finding algorithm as for the "Fit-Track" method is used with the only difference that the value for  $\theta_{in}$  is calculated from the fit of  $\theta_{out}$  vs.  $x_{MW3}$ :

The parameters of the linear fit are used for the calculation of  $\theta_{in}$  :

$$\theta_{in} = \alpha - a \cdot x_{MW3} - b$$

With **a** being the slope and **b** the offset of the fit. This method prevents from adding up the errors from  $\theta_{in}$  measurement.

$\alpha$  corresponds to the mean value of the  $\theta_{out}$  from the fit of  $\theta_{out}$  vs.  $x_{MW3}$ .

## 4 Plots

In this section all the plots for the various track finding algorithms are presented. For the calculation of the  $\theta_{in}$  angle MWPC1 and MWPC2 are used. Alternatively MWPC0 and MWPC2 could be used, to get a longer lever arm (work in progress ...).

## 5 Relative momentum resolution ”Advanced Fit-Track-Method”

The momentum resolution is calculated from the radius-calculation as  $\rho \sim p$ . From that follows:

$$\frac{\Delta p}{p} = \frac{\Delta \rho}{\rho}$$

For the evaluation of the resolutions for the various sweep runs the two dimensional plot ”MWPC3.fX versus GLAD Radius” is projected on the abscissa. The resulting 1D plot is fitted with a gaussian. The mean value from the fit corresponds to  $\rho$  and the  $\sigma$  to  $\Delta\rho$  respectively.

Runnr.	$\bar{\rho}$	$\sigma$	rel. resolution
39	6.48911e+03	2.13410e+01	3.289e-03
40	6.42396e+03	1.56313e+01	2.433e-03
42	6.20033e+03	1.42716e+01	2.301e-03
44	5.86854e+03	1.29449e+01	2.206e-03
46	5.57125e+03	1.31369e+01	2.358e-03
48	5.30203e+03	1.07044e+01	2.018e-03
51	5.06232e+03	1.07182e+01	2.117e-03
53	6.64556e+03	1.66141e+01	2.500e-03
55	7.08710e+03	1.91895e+01	2.708e-03
57	7.57474e+03	2.16135e+01	2.853e-03
59	8.15089e+03	2.22151e+01	2.725e-03
61	8.81055e+03	2.72038e+01	3.088e-03

With mean relative resolution  $\frac{\Delta \rho}{\rho} = 2.55\text{e-}03$ .

## 6 Limiting Radius/Momentum resolution factors

The radius/momentum resolution is limited by:

- Energy straggling
- Angular straggling
- Angular resolution of MWPC1/2
- position resolution of MWPC3 (higher order??)

## 6.1 Energy straggling

For the error calculation the mean energy inside the GLAD was used and the corresponding standard deviation. Generally for a charged particle drifting through a magnetic field the radius of the curved path the particle is following is defined as:

$$\rho = \frac{\gamma \cdot \beta \cdot m}{q \cdot B}$$

(considering  $c = 1$ )

Energy straggling has an effect on  $\beta$  and  $\gamma$  respectively. The measurement uncertainty with respect to  $\beta$  can be calculated as follows:

$$\frac{d\rho}{d\beta} = \frac{1}{(\sqrt{1-\beta^2})^3} \cdot \frac{m}{qB}$$

$$\Delta\rho_\beta = \frac{d\rho}{d\beta} \cdot \Delta\beta = \frac{\Delta\beta}{(\sqrt{1-\beta^2})^3} \cdot \frac{m}{qB}$$

with relative measurement uncertainty  $\frac{\Delta\rho_\beta}{\rho} = 5.434e - 04$

## 6.2 Angular straggling

For the error calculation originating from angular straggling it is considered only angular straggling starting from the backend of the MWPC1. That means for this error calculation it is assumed to have a perfect focussed beam undergoes no broadening until it hits the MWPC1 (always at the same x-y-z position). Angular straggling broadens the beam focus and affects therefore both  $\Theta_{in}$  and  $\Theta_{out}$ .

(angular straggling for  $\Theta_{in}$  can be neglected, higher order...)

For the calculation of measurement uncertainty with respect to  $\Theta_{out}$  we use the simplified geometrical formula of the radius:

$$\rho = \frac{L_{eff}}{2 \cdot \sin(\frac{\Theta_{in} + \Theta_{out}}{2})}^3$$

From that follows:

$$\Delta\rho_{\Theta_{out}} = -\rho \cdot \frac{1}{2 \cdot \tan(\frac{\Theta_{in} + \Theta_{out}}{2})} \cdot \Delta\Theta_{out}$$

with  $\Delta\Theta_{out} = 3.401e - 04$ . This is the value calculated with LISE++ from MWPC1 to the very center of GLAD. Hence:

$$\left| \frac{\Delta\rho_{\Theta_{out}}}{\rho} \right| = \frac{1}{2 \cdot \tan(\frac{\Theta_{in} + \Theta_{out}}{2})} \cdot \Delta\Theta_{out} = 1.079e-03$$

## 6.3 Angular resolution of MWPC1/2

$$\Delta\rho_{\Theta_{in}} = -\rho \cdot \frac{1}{2 \cdot \tan(\frac{\Theta_{in} + \Theta_{out}}{2})} \cdot \Delta\Theta_{in}$$

with  $\Delta\Theta_{in} = \frac{2 \cdot \Delta x}{L}$ <sup>4</sup> and L the (z-)distance between MWPC1 and MWPC2 (= 575mm).

---

<sup>3</sup>on the following pages I set  $\Theta_{in} = 0$  and  $\Theta_{out}$  to the value given by the GLAD field calculator(Mass = 12, Charge = 6, Energy = 400 A/MeV, Current = 1444), see <http://web-docs.gsi.de/~land/glad/>.

<sup>4</sup> $\Theta_{in} = \frac{x_2 - x_1}{L}$ ,  $\Delta\Theta_{in} = \left| \frac{d\Theta_{in}}{dx_2} \right| \cdot \Delta x_2 + \left| \frac{d\Theta_{in}}{dx_1} \right| \cdot \Delta x_1 = \frac{2 \cdot \Delta x}{L}$

With  $\Delta x = 0.1mm$  it follows:

$$\left| \frac{\Delta \rho \Theta_{in}}{\rho} \right| = 1.104e-03.$$

Adding up the above errors quadratically we get:

$$\left| \frac{\Delta \rho}{\rho} \right| = \sqrt{(5.434 \cdot 10^{-4})^2 + (1.079 \cdot 10^{-3})^2 + (1.104 \cdot 10^{-3})^2} = 1.64 \cdot 10^{-3}$$

## 6.4 Limiting Radius resolution factors on data

For this subsection RUN 53 (with GLAD current = 1444A) is taken in account.

From the table of relative radius resolution we see that for RUN 53 it corresponds to 2.500e-03. The contribution from angular resolution of MWPC1/2 is 1.104e-03 (see previous section). The major limiting factor, the angular straggling can be retrieved from the resolution of theta\_out. It has to be considered that the resolution of theta\_out is affected by the beam broadening before the MWPC1. To account for that it has to be analyzed the impact of theta\_in on theta\_out.

Therefore an offset of 1 mrad is added to theta\_in and the mean values for theta\_out can be compared :

- theta\_out without shift:  $3.13257 \cdot 10^{-1}$
- theta\_out with 1 mrad theta\_in shift:  $3.13912 \cdot 10^{-1}$
- difference:  $6.55 \cdot 10^{-1} \text{mrad}$

That means we have a translation factor (for small angles) of 0.655 for theta\_in to theta\_out.

The error calculation in the previous section predicts following angular straggling error:

$$2.5 \cdot 10^{-3} = \sqrt{(1.104 \cdot 10^{-3})^2 + \left( \left| \frac{\Delta \rho \Theta_{out}}{\rho} \right| \right)^2}$$

follows:

$$\left| \frac{\Delta \rho \Theta_{out}}{\rho} \right| = 2.24 \cdot 10^{-3}$$

$$\Rightarrow 2.24 \cdot 10^{-3} \cdot \tan(0.15625) \cdot 2 = 7.1 \cdot 10^{-4} = \Delta \theta_{out}$$

The angular resolution of theta\_out from data is 1.78045E-03. From this value the angular beam broadening (multiplied by the translation factor) before MWPC1 has to be subtracted:

$$\Delta \theta_{out} = 1.78045 \cdot 10^{-3} - 0.655 \cdot 1.61086 \cdot 10^{-3} = 7.253 \cdot 10^{-4}$$

This result coincides well with the predicted one and confirms that the predominant factors for the limiting radius resolution are angular straggling and the angular resolution of MWPC1/2.

## 7 Scalability of the field

Using the sweep runs (39-61) with different GLAD currents, the scalability of the B-Field can be analyzed. In figure 12  $B_{\rho}$  from GLAD calculator divided by the mean radius is

plotted against the according current values.  
 Taking the assumption that:

Figure 12

$B = current \cdot k$  (with  $k$  being a constant)

we get from the fit in 12:

slope = 0.000610713

offset = 0.0709244

When plotting the proportional factor  $k$  (which is equal to  $\frac{Brho}{I\rho}$ , with  $Brho$  from GLAD calculator and  $\rho$  equal to the mean radius for each run) for each RUN versus the current and adding the proportional factor from the fit as a straight line, we can see in figure 13 that the factor  $k$  from the fit seems to be slightly underestimated.

Figure 13

## 8 Z versus A/q calculations

In this section the target RUNs 82,83,86,88 are analyzed with GLAD current = 1444 A, target = CH2 12.29 mm.

Data is taken for the x-position on MW1,MW2 and MW3, time difference between START and TOFW Detector and charge value from TWIM Music.

The radius of curvature in GLAD is computed using the "Advanced Fit Track" method. The time of flight is calculated using the time difference between START and TOFW with the respective offsets (for the TOF detector pads) and subtracting from that the time of flight between START detector and target. The latter is calculated using  $\beta = 0.714549 (\equiv 400 \text{ A/MeV})$  and as distance between START and target 1183.25 mm.

Offsets used for RUNs 82 and 83 ( using sweep RUNs 39-61) and for RUNs 86 and 88 (using sweep run 36), respectively:

Detnr. TOFW	Time offset 39-61 [ns]	Time offset 36 [ns]
1	114.916	114.4
2	113.592	113.588
3	116.172	116.132
4	114.396	114.358
5	115.279	115.261
6	115.910	115.886
7	116.751	116.734
8	116.002	115.982
9	114.242	114.222
10	115.822	115.801
11	112.410	112.402
12	115.801	115.786
13	113.355	113.347
14	114.925	114.917
15	113.514	118.516
16	112.817	117.823
17	114.214	119.217
18	111.899	116.913
19	113.050	118.063
20	112.578	117.591
21	116.283	121.295
22	116.685	121.690
23	115.884	120.896
24	115.922	120.931
25	114.642	119.649
26	114.207	119.225
27	114.212	119.274

The proceeding for the Z versus A/q calculations are:

1. Plot without any cuts/restrictions Z versus Radius using the "Fit-Track" method (see [14](#) ).
2. From that plot identify the various isotopes and cut on them.
3. Plot for each isotope theta\_out vs x\_3 and make a linear fit (see [17](#)).
4. Feed the "Advanced Fit-Track" method with the parameters of the fit for the various isotopes (which you can separate using the previously selected cuts).
5. Calculate beta (using the above TOFW offsets) for the various isotopes and plot Z versus A/q.

Figure 14: Z versus Radius for RUN 88.

(a) theta\_out vs xMW3 for 10B.

(b) theta\_out vs xMW3 for 11B.

(c) theta\_out vs xMW3 for 11C.

(d) theta\_out vs xMW3 for 12C.

Figure 15: theta\_out vs xMW3 for isotopes.

The cuts on the various isotopes in 14 are:

- 10B:  $4.49 < Z < 5.35$  and  $6131 < \rho < 6786$
- 11B:  $4.34 < Z < 5.48$  and  $6820 < \rho < 7505$
- 11C:  $5.54 < Z < 6.61$  and  $5720 < \rho < 6216$
- 12C:  $5.42 < Z < 6.7$  and  $6247 < \rho < 6850$

Using this cuts we get following fit parameters for the various isotopes:

Isotope	$\alpha$	a (= slope)	b (=offset)
<b>10B:</b>	0.3202	0.000143964	0.327888
<b>11B:</b>	0.2934	0.000140786	0.313639
<b>11C:</b>	0.3461	0.000146043	0.340846
<b>12C:</b>	0.3178	0.000143976	0.326675

Separating the isotopes by the above charge and radius cuts and using the appropriate  $\alpha$ , a and b parameters the Radius gets recalculated via the "Advanced Fit-Track" method. The new value for the radius is now used in the A/q calculation:

$$A/q = \frac{B \cdot \rho \cdot e}{\gamma \cdot \beta \cdot c \cdot u}$$

with:

$e$ : elementary charge =  $1.602176634 \cdot 10^{-19} \text{C}$

$c$ : speed of light =  $299792458 \text{ m/s}$

$u$ : atomic mass unit =  $1.66053906660 \cdot 10^{-27} \text{kg}$

In figure 16 the separated isotopes are shown.

Figure 16: Z versus A/q for run 88 with target CH2 12.29 mm.

## 8.1 Limiting Mass number resolution factors<sup>5</sup>. $\Rightarrow$ REDO! I use $\gamma$ \_fixed. Error calculation simplifies...

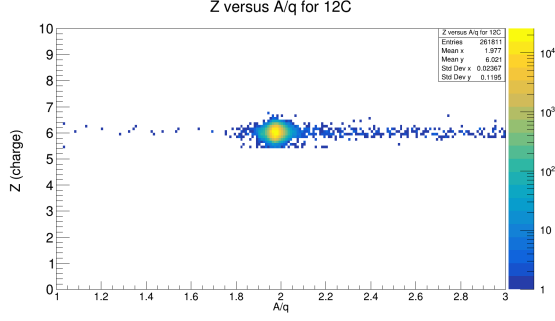

From the formula:

$$A/q = \frac{B \cdot \rho \cdot e}{\gamma \cdot \beta \cdot c \cdot u}$$

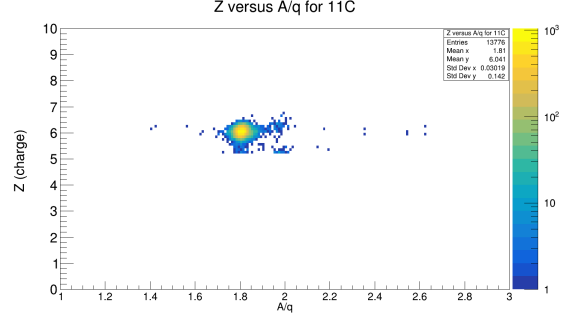

we can see that the determination of A/q is limited by the radius  $\rho$  and time measurement and path calculation .

---

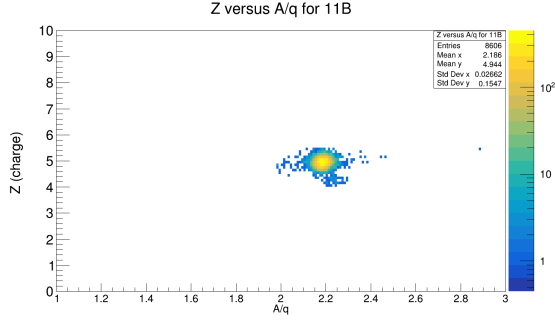

<sup>5</sup>This analysis was done with RUN 88, CH2 target, 12.29mm, GLAD current = 1444 A on the isotope <sup>12</sup>C

(a)  $5.4 < q < 6.8$ ;  $6295 < \rho < 6768$

(b)  $5.2 < q < 6.8$ ;  $5774 < \rho < 6189$

(c)  $4 < q < 5.5$ ;  $6888 < \rho < 7363$

(d)  $4 < q < 5.4$ ;  $6266 < \rho < 6735$

Figure 17: Z versus A/q for runs 82, 83, 86, 88 with target CH2 12.29 mm.

That means:

$$\left| \frac{\Delta A/q}{A/q} \right| = \sqrt{\left| \frac{\Delta A/q_p}{A/q} \right|^2 + \left| \frac{\Delta A/q_t}{A/q} \right|^2 + \left| \frac{\Delta A/q_s}{A/q} \right|^2}$$

with:

$$\left| \frac{\Delta A/q_p}{A/q} \right| = \left| \frac{\Delta \rho}{\rho} \right| = 1.64 \cdot 10^{-3}$$

and

$$\left| \frac{\Delta A/q_t}{A/q} \right| = \frac{\Delta t}{t}$$

$\Delta t$  corresponds to the resolution of the time measurement of the TOFW and  $t$  the time of flight from target to the TOFW ( $\sim 35ns$ ).

and :

$$\left| \frac{\Delta A/q_s}{A/q} \right| = \frac{\Delta s}{s} \text{ with } \Delta s \sim \Delta \rho \text{ and } s \text{ the pathlength from target to TOFW } (\sim 7500mm).$$

The time resolution is calculated by taking the mean value of  $\sigma_t$  of the most hit TOFW detectors (run 88):

- 10B: most hit detnr: 12,13,14,15,16;  $\sigma_t = 9.764 \cdot 10^{-2}ns$
- 11B: most hit detnr: 8,9,10,11,12;  $\sigma_t = 1.008 \cdot 10^{-1}ns$
- 11C: most hit detnr: 16,17,18,19;  $\sigma_t = 1.009 \cdot 10^{-1}ns$

- 12C; most hit detnr: 13,14;  $\sigma_t = 9.834 \cdot 10^{-2} ns$

From that follows a relative error due to the time resolution (assuming for all isotopes the same mean time of flight):

- 10B:  $2.79 \cdot 10^{-3}$
- 11B:  $2.88 \cdot 10^{-3}$
- 11C:  $2.88 \cdot 10^{-3}$
- 12C:  $2.81 \cdot 10^{-3}$

$$\left| \frac{\Delta A/q_s}{A/q} \right| = \frac{\Delta s}{s} = \frac{\Delta \rho}{s} = 1.421 \cdot 10^{-3}$$

Summing up all errors quadratically we get for the isotopes:

- 12C:  $\left| \frac{\Delta A/q}{A/q} \right| = \sqrt{(2.81 \cdot 10^{-3})^2 + (1.64 \cdot 10^{-3})^2 + (1.421 \cdot 10^{-3})^2} = 3.55 \cdot 10^{-3}$
- 11C:  $\left| \frac{\Delta A/q}{A/q} \right| = \sqrt{(2.88 \cdot 10^{-3})^2 + (1.64 \cdot 10^{-3})^2 + (1.421 \cdot 10^{-3})^2} = 3.61 \cdot 10^{-3}$
- 11B:  $\left| \frac{\Delta A/q}{A/q} \right| = \sqrt{(2.88 \cdot 10^{-3})^2 + (1.64 \cdot 10^{-3})^2 + (1.421 \cdot 10^{-3})^2} = 3.61 \cdot 10^{-3}$
- 10B:  $\left| \frac{\Delta A/q}{A/q} \right| = \sqrt{(2.79 \cdot 10^{-3})^2 + (1.64 \cdot 10^{-3})^2 + (1.421 \cdot 10^{-3})^2} = 3.53 \cdot 10^{-3}$

## 9 Revised A/q resolution (with fixed $\gamma$ )... work in progress

Looking at the formula:

$$A/q = \frac{B \cdot \rho \cdot e}{\gamma \cdot \beta \cdot c \cdot u}$$

the measured observables are: s,t (which give  $\beta$ ) and  $\rho$  (from position measurements in MW1,2,3 and Z (from TWIM-Music). On the other side  $\gamma$  remains a fixed parameter as the B-Field is too. The relativistic B-Field is determined once by the GLAD calculator. It contains already a fixed  $\gamma$  value, therefore the formula has to be divided by a fixed  $\gamma$  value too.

In comparison to the non-relativistic formula the above one has an additional factor of  $\gamma$ . While the pathlength and the time of flight are measured in the lab frame ( $\rho$  can be neglected, as it is perpendicular to the flight direction and therefore is the same in the particle and lab frame), the B-Field is calculated in the GLAD calculator in the particle frame. The

particle in its own frame is exposed to a higher B-Field by a factor of  $\gamma$ . Hence, if we want to determine the resting mass we need to divide the B-Field by  $\gamma$ .

In figure 18 the calculated  $A/q$  values versus the time of flight are plotted for each isotope and each event. From the plots we get following resolutions for  $A/q$  and for  $\rho$  (for RUN 88):

Isotope	$A/q$	$\frac{\Delta A/q}{A/q}$
<b>10B:</b>	1.96089	0.004735
<b>11B:</b>	2.13816	0.004410
<b>11C:</b>	1.80957	0.004301
<b>12C:</b>	1.96433	0.003220

## 10 Set by step discrimination of the isotopes

- Plot the charge values of the particles going through TWIM Music and make a gauss fit on them. The intersection of the two gaussians is the charge cut between  $Z = 5$  and  $Z = 6$ .
- Plot  $A/q$  versus time of flight for both charges using the derived formula for  $\rho$
- Project the plot to the  $A/q$  axis and make two gaussian fits on both  $Z = 5$  and  $Z = 6$ . The intersection between the gaussians give you the mass cuts between 11C and 12C (10B and 11B).
- Now plot for each isotope  $\theta_{out}$  vs  $x_{MW3}$ . Make a linear fit on it and extract from it the parameters  $\alpha$ ,  $a$  and  $b$  (for the formula:  $\theta_{in} = \alpha - a \cdot x_{MW3} - b$ )
- Now calculate again  $A/q$  for each isotope using the formula for  $\rho$  but now with the formula for  $\theta_{in}$  from the previous step

# Appendices

## A Radius resolution with minimal constraints

When using minimal constraints (one single fX entry in MWPC0,1,2,3; instead of requiring also one single entry in fY for MW0,1,2,3) for events in sweep RUN 39-61 the resolution for the radius determination improves:

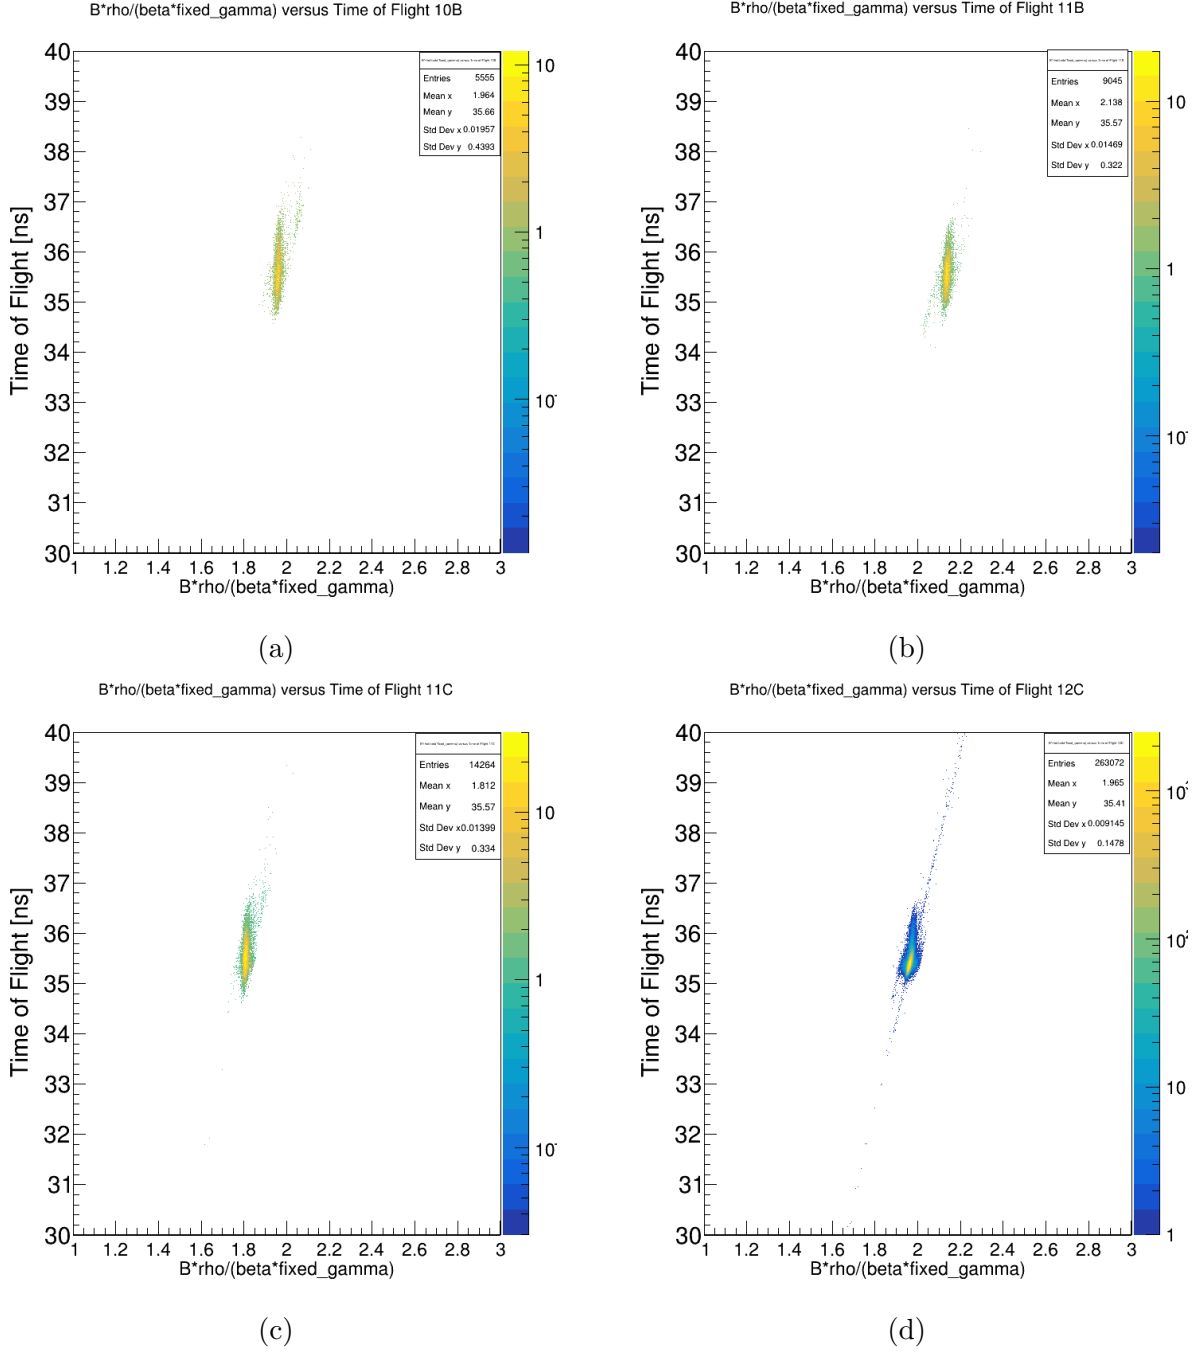

Figure 18: Time of Flight versus  $A/q$  with  $\beta$  from time measurement and flightpath reconstruction and fixed  $\gamma$  for RUN 88.

Runnr.	$\bar{\rho}$	$\sigma$	rel. resolution
39	6.48993e+03	2.30085e+01	3.545e-03
40	6.42478e+03	1.23238e+01	1.918e-03
42	6.20135e+03	1.16977e+01	1.886e-03
44	5.86911e+03	1.05839e+01	1.803e-03
46	5.57055e+03	9.45711e+00	1.697e-03
48	5.30096e+03	8.63127e+00	1.628e-03
51	5.06178e+03	8.99078e+00	1.776e-03
53	6.64685e+03	1.30785e+01	1.967e-03
55	7.08715e+03	1.56974e+01	2.214e-03
57	7.57535e+03	1.68392e+01	2.222e-03
59	8.15170e+03	1.93779e+01	2.377e-03
61	8.81023e+03	2.33200e+01	2.646e-03

With the exception of RUN 39 (why??) the resolution improve with low constraints. This could be due to the lower angular straggling impact when particles don't hit/interact with the y-wires of the MWPCs.

## B Time of Flight Calibration

To make the Time of Flight(ToF) calibration, following recipe was used:

Calculate the ToF resolution = pathlength(for plastic)/(velocity) where the pathlength is a fixed parameter for each plastic while velocity = pathlength/calibrated time of flight (for each event). As ToF and resolution we get (using sweep RUNS 39-61):

Detectornr. TOFW	mean ToF [ns]	Std_dev [ns]
1	4.06321e+01	6.28229e-02
2	4.06324e+01	5.53876e-02
3	4.06304e+01	8.08743e-02
4	4.06301e+01	6.90470e-02
5	4.06281e+01	8.67233e-02
6	4.06272e+01	6.83199e-02
7	4.06262e+01	8.08281e-02
8	4.06264e+01	8.28594e-02
9	4.06242e+01	8.43386e-02
10	4.06240e+01	7.83839e-02
11	4.06224e+01	1.41360e-01
12	4.06236e+01	1.16904e-01
13	4.06194e+01	1.03966e-01
14	4.06205e+01	9.27237e-02
15	4.06174e+01	8.37932e-02
16	4.06166e+01	9.08337e-02
17	4.06155e+01	9.05575e-02
18	4.06131e+01	1.20459e-01
19	4.06106e+01	1.01854e-01
20	4.06130e+01	1.21520e-01
21	4.06119e+01	2.46357e-01
22	4.06103e+01	9.69992e-02
23	4.06092e+01	9.85493e-02
24	4.06069e+01	1.38125e-01
25	4.06062e+01	1.01997e-01
26	4.06065e+01	1.00157e-01
27	4.06030e+01	7.90385e-02

This gives a mean standard deviation of  $\sigma_t = 9.907 \cdot 10^{-2}$
